FICHA TÉCNICA

Nombre de la publicación	Estimaciones y proyecciones de población. Proyecciones sub-nacionales 2000-2030.
Objetivo general del producto	Dar a conocer las estimaciones y proyecciones de la población por edad y sexo; y algunos indicadores de estructura de la población, de regiones y provincias, para el período 2000-2030.
Descripción general del producto	En la publicación se dan a conocer los resultados de las estimaciones y proyecciones de población por edades, sexo, indicadores de estructura de la población para los años 2000-2030. Así, también se describe la metodología utilizada para el desglose de dichas proyecciones, a partir de los resultados obtenidos en las estimaciones y proyecciones de población por grupos de edad y sexo, del período 1950-2100, presentadas en el Tomo I.
Año de inicio del producto estadístico	2015
Publicación de la metodología	Pertenece a la serie de publicaciones que dan cuenta de los resultados y la metodología utilizada para la elaboración de las estimaciones y proyecciones de población 1950-2100.
Tipo de levantamiento	Recopilación e Integración de información censal y de revisión de fuentes de información relacionadas con el nivel y estructura de los factores demográficos.
Periodicidad del levantamiento de la información	Revisión anual
Cobertura geográfica	Total nacional, regional y provincial
Fuentes de la información	Registros administrativos, encuestas demográficas y de salud, encuestas de hogares, censos de población de República Dominicana, información sobre ¿????
Fecha de la publicación	Abril 2016
Medios utilizados para la difusión de las publicaciones	Impreso, digital, y publicación en línea a través de la página web de la ONE. PRESENTACIÓN

Este volumen de las **Estimaciones y proyecciones subnacionales de población 2000-2030**, es un trabajo que da continuidad a los esfuerzos que se vienen realizando desde la Oficina Nacional de Estadística, a fin de dar las herramientas necesarias a los usuarios para una mejor planificación, y, sin duda alguna será de buen provecho, sobre todo para la desagregación de las políticas públicas.

Ya en el 2009 la ONE presentó por primera vez unas estimaciones y proyecciones sub-nacionales de población, en la cual se utilizó el método de los componentes desagregados a nivel de provincia, con este método en que convergen las variables demográficas que determinan el cambio de la población se procura tener mejores estimaciones.

Estas estimaciones y proyecciones de población arrojan resultados por regiones y provincias sobre la población por año calendario, y, grupos quinquenales de edad. Del mismo modo, se presentan indicadores de la estructura de la población para las mismas áreas político-administrativas.

Se reconoce ampliamente que las proyecciones de población, por sexo y edad, tanto al nivel nacional como para las diferentes áreas geográficas y político-administrativas de un país, constituyen una herramienta de gran utilidad para la planificación económica y social.

La evolución probable de la población total en el futuro próximo es un elemento fundamental para la determinación de las demandas sociales, y para la elaboración de planes y programas en diversos campos del desarrollo; tales como la generación de empleos productivos, la producción de bienes y servicios económicos, la construcción de establecimientos educativos y de salud, la formación de recursos humanos en estas áreas, la construcción de viviendas y soluciones habitacionales, entre otros de similar importancia.

Como es de suponer, la calidad y utilidad potencial y efectiva de las proyecciones de población dependen estrechamente del grado en que estén basadas en análisis cuidadosos de las tendencias, pasadas y recientes, de los componentes del cambio demográfico -fecundidad, mortalidad y migración-, y sus relaciones con los aspectos sociales, culturales y económicos, así como de la consideración prestada a las tendencias y relaciones al formular las hipótesis de evolución futura de los componentes indicados.

El cumplimiento de estos requisitos descansa a su vez en la disponibilidad de información confiable, detallada y oportuna, sobre las variables de interés, por lo que a medida que se producen nuevas y mejores estadísticas se plantea la necesidad de la revisión y actualización de las proyecciones.

La presente publicación contiene información útil para el cálculo de indicadores; entre éstos los que se refieren al seguimiento de los acuerdos internacionales, pues ofrece una estimación de la población expuesta para cada grupo etáreo.

Adicionalmente, en el proceso de estimación, evaluación y análisis de los componentes demográficos, para el período base de la proyección, se diseñaron aplicaciones especiales para planillas de cálculo electrónico en **Excel**, las cuales permiten obtener y compatibilizar las estimaciones provenientes de los métodos indirectos de estimación demográfica, que sirvieron de insumo para la proyección de la población.

Pablo Tactuk
Director Nacional

INTRODUCCIÓN

El equipo técnico de la ONE ha hecho un trabajo extraordinario para elaborar las proyecciones sub-nacionales y conciliarlas con la proyección nacional (a disposición del público desde el 2014); esto debido a la gran cantidad de información desagregada que hay que evaluar.

El trabajo fue hecho en dos etapas. En la primera se definieron las poblaciones provinciales ajustadas a los años 2000 y 2010. Con la información demográfica del periodo se hizo una conciliación, para estimar la población por provincia para los años comprendidos entre 2000 y 2010.

En la segunda etapa se proyectaron las provincias partiendo del año 2010. Los procedimientos adoptados fueron los tradicionales en demografía, con utilización de tasas de mortalidad, fecundidad y saldos migratorios (Método de los Componentes). Todos estos procedimientos son explicados con más detalle en adelante.

En el caso de la mortalidad, fueron elaboradas un juego de cinco tablas de mortalidad para igual número de regiones demográficas, que no necesariamente coinciden con las regiones de planificación. Para este fin las provincias fueron agrupadas de acuerdo a su nivel de pobreza, cuya clasificación la hizo el Ministerio de Economía, Planificación y Desarrollo, en el estudio *Mapa de Pobreza en la República Dominicana 2014*, al proyectar cada provincia fue sometida al patrón de mortalidad que presenta la región demográfica dentro de la cual formaba parte.

En estos momentos, internacionalmente, se está planteando iniciar la evaluación y seguimiento de un grupo de indicadores, que se han denominado Indicadores de Desarrollo Sostenible (ODS), y estas proyecciones van a ser de gran utilidad, tanto para la definición de los niveles de partida, como para el seguimiento.

1. SUPUESTOS INICIALES

1.1 Población base de las provincias

Para definir la población base de cada provincia, en el año 2010, se trasladó la población del censo de ese mismo año a mitad de año, estas poblaciones, por grupos de edad y sexo, fueron conciliadas con la correspondiente población del total del país, ya estimada en las proyecciones nacionales mediante la utilización de una tabla de contingencia.

La suposición básica de estos procedimientos es que en un período de cinco meses (entre mitad de año y la fecha del censo), los cambios ocurridos en la estructura por edad de la población fueron seguramente no significativos, y la omisión diferencial por sexo y edad no difiere mucho entre las provincias. De todas formas, no hay disponibles otros datos necesarios para proceder de otra manera.

1.2. Mortalidad y regionalización de las provincias

Desde el año 2005 la ONE viene registrando sistemáticamente las defunciones que se registran en todas las Oficialías del Estado Civil, y en la actualidad se dispone de una base de datos con la serie que comprende el período 2001-2014. De la explotación de la base de datos defunciones, se dispuso de una serie de tabulados por grupos de edad, sexo y año calendario, de las defunciones por provincia.

Los datos sobre defunciones, a pesar de los avances que se han tenido en el país, presentan aún de un alto grado de sub-registro, lo cual dificulta muchas veces la posibilidad de hacer análisis a niveles de divisiones territoriales pequeñas. Así, conociendo estas limitantes, al igual que en las proyecciones sub-nacionales realizadas en el 2009, en esta oportunidad también se optó por agrupar las provincias de acuerdo con su grado de desarrollo, asumiendo que los patrones de mortalidad serían semejantes para elaborar juegos de tablas de vida por regiones demográficas, estas regiones no necesariamente coinciden con las regiones políticas del país.

Fueron creadas cinco regiones. El criterio para la creación de estas regiones demográficas fue su grado de pobreza, cuya clasificación hizo el Ministerio de Economía Planificación y Desarrollo en el estudio *Mapa de Pobreza en la Republica Dominicana 2014*.

Para la elaboración de las tablas de vida para los momentos censales 2002 y 2010 de las regiones creadas, se cumplió con el rigor de hacer una evaluación particular de cada una de éstas, y, mediante técnicas indirectas de análisis demográfico¹, se corrigió la mortalidad de los mayores de cinco años; se obtuvieron estimaciones por sexo de la mortalidad infantil $-q_0-$ y los factores de separación $-f_0-$, que son insumos necesarios para la proyección de la mortalidad.

Al proyectar cada provincia ésta fue sometida al patrón de mortalidad que presenta la región demográfica de la cual formaba parte.

2.3 Fecundidad

La fecundidad en el país, así como en el resto de los países en América Latina, ha ido descendiendo desde hace décadas. Esto se ha constatado en las diferentes encuestas demográficas que se han realizado desde hace décadas, y en las estimaciones realizadas a partir de la información censal.

A pesar de los grandes avances que ha tenido el país en materia del registro de los hechos vitales, todavía hay grandes barreras por superar. Los niveles del sub-registro de las estadísticas vitales aún son altos, y se supone que esto no debería estar sucediendo, y menos en un país donde casi la totalidad de los nacimientos ocurren en centros hospitalarios (públicos y privados).

La Oficina Nacional de Estadística tiene un sistema de registro de los hechos vitales (nacimientos, defunciones, matrimonios y divorcios) que se registran en todas las Oficialías del Estado Civil, a lo largo y ancho del país, y hasta la fecha contiene íntegramente el seriado desde el año 2001 hasta el 2014

Para la estimación de la fecundidad en las provincias, tanto en su nivel como en su estructura, se ha apelado a la aplicación de técnicas indirectas de análisis demográfico, que se deriva de la inclusión en la boleta censal de preguntas especiales para obtener información sobre la fecundidad de las mujeres. Estas preguntas son las de hijos nacidos en el último año, y los hijos que han declarado haber tenido las mujeres a lo largo de toda su vida.

El procedimiento indirecto empleado, para estimar la fecundidad, se denomina el método P/F, y fue desarrollado por W. Brass (1974)². El método P/F relaciona la información retrospectiva sobre el número de hijos tenidos a lo largo de la vida de las mujeres, con la fecundidad del último año; de esto se obtiene un factor para corregir las tasas de fecundidad de la fecundidad actual.

Mediante la utilización del método P/F, con la información de los censos de los años 2002 y 2010, se obtuvieron para cada provincia las tasas específicas de fecundidad³ 5fx de las mujeres, entre las edades desde 15 a 49 años, y fueron calculadas las correspondientes tasas globales de fecundidad⁴ (TGF).

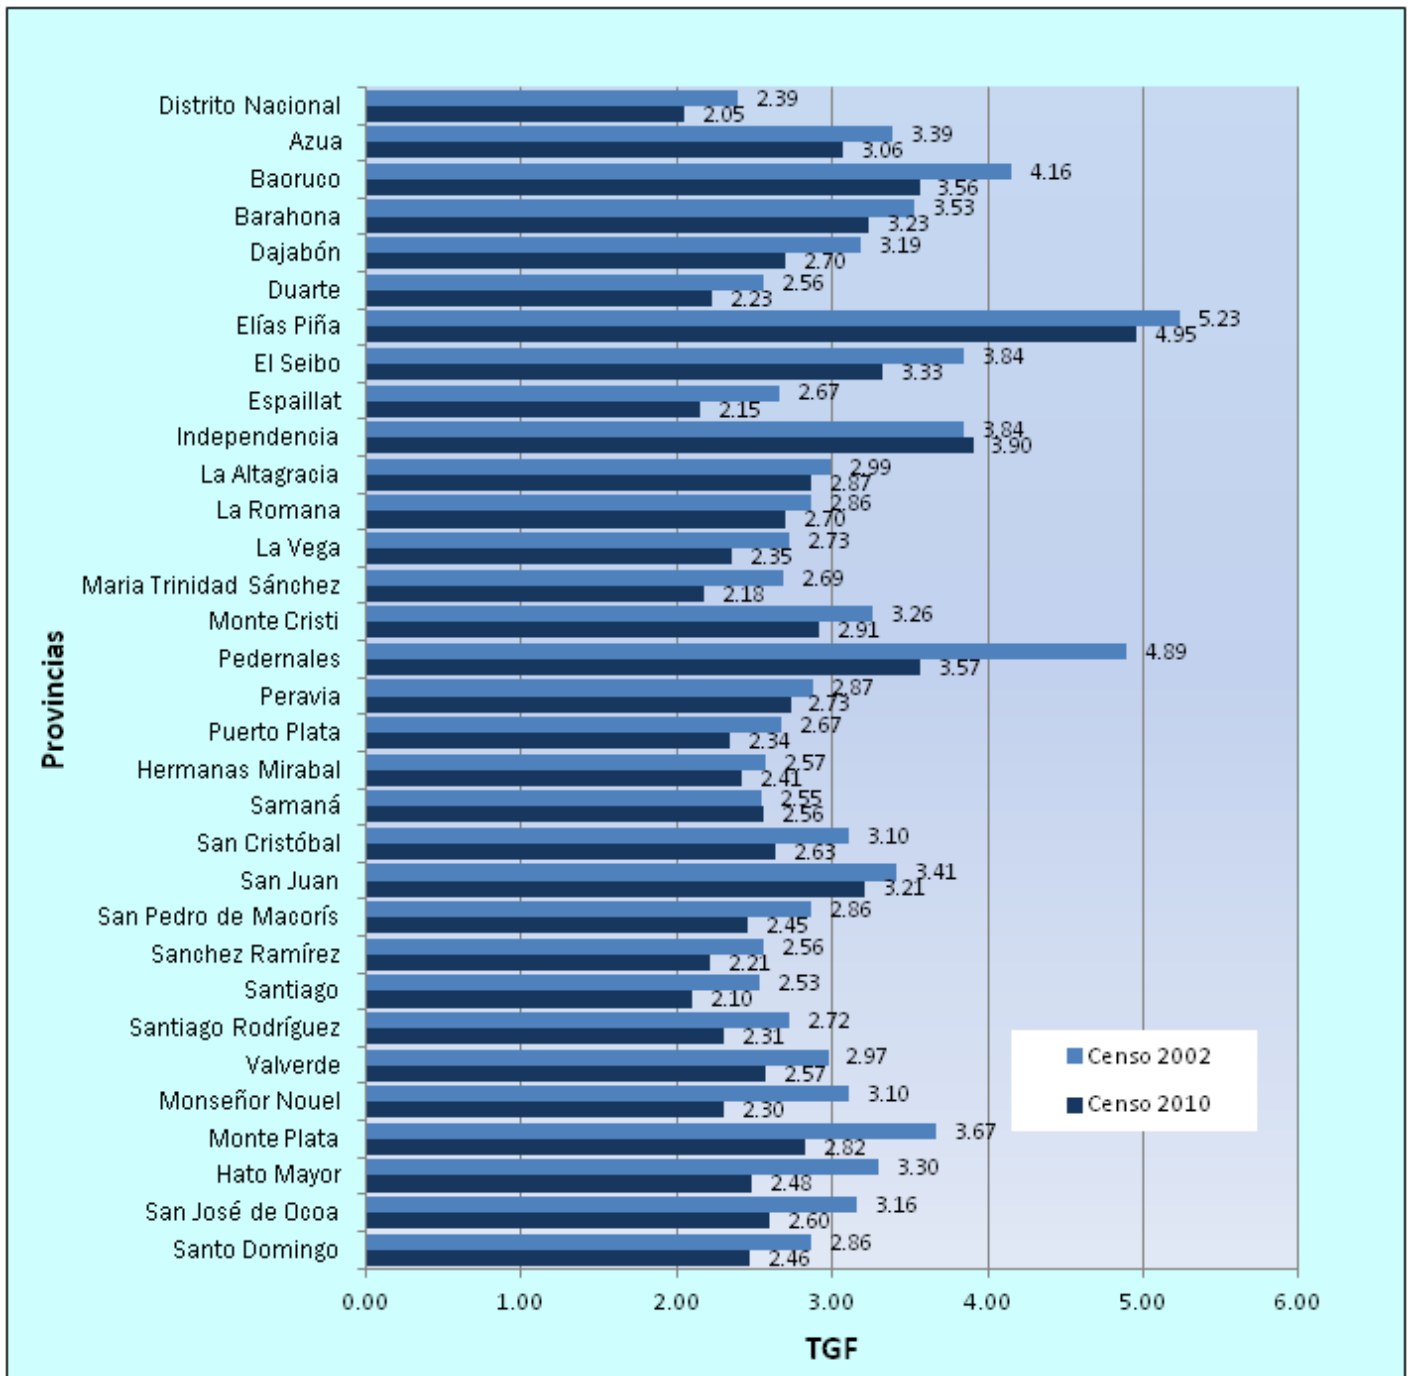

² Manual X de Naciones Unidas (1983).

³ Se calcula como el cociente entre los nacimientos de las mujeres un grupo de edades, para un período determinado (generalmente un año), sobre la población femenina media del mismo grupo. Generalmente se utilizan tasas por grupos quinquenales de edad de las madres, desde los 15 a los 49 años cumplidos de edad.

⁴ Es el número promedio de hijos que tendría una mujer de una cohorte hipotética de mujeres que durante su vida fértil tuvieran sus hijos de acuerdo con las tasas de fecundidad por edad del período en estudio y que no estuvieran sometidas a riesgos de mortalidad desde el nacimiento hasta la finalización del período fértil. Se calcula como la suma de las tasas de fecundidad por grupos de edades quinquenales de las madres, multiplicadas por cinco.

Gráfico 5

REPÚBLICA DOMINICANA: Tasa global de fecundidad por provincias. Censos del 2002 y 2010.

2.4 Migración

La migración, por provincia, está compuesta por dos componentes: la migración interna y la migración internacional; teniendo cada una sus propias particularidades y por lo tanto requieren un análisis por separado.

El saldo migratorio total para cada provincia es el resultado de la suma de los saldos migratorios interno (interprovincial) y del saldo migratorio internacional. El saldo de la migración total en el país debe ser igual al saldo neto migratorio internacional, debido a que la suma de todos los saldos internos de las provincias se anulan entre sí, y su resultado es igual a cero, ya que los que emigran de una determinada provincia son absorbidos como inmigrantes en otras.

2.4.1 Migración internacional

Para la migración internacional se ha asumido que, en ausencia de información precisa a nivel de provincia de los patrones migratorios hacia y desde el exterior del país, los saldos migratorios internacionales del total país, de la proyección nacional, afectan por igual a todas las provincias, por lo que fueron distribuidos proporcionalmente por edad y sexo a la población de cada provincia.

2.4.2 Migración interna

Procesando la base de datos de los censos de los años 2002 y 2010, se obtuvo la cantidad de migrantes interprovinciales recientes (emigrantes e inmigrantes) mayores de cinco años, y por ende los saldos de la migración interna de los últimos cinco años previos al censo, o sea para los períodos 1997-2002 y 2005-2010, fueron segregados por provincia, por sexo y grupos quinquenales de edad.

2.4.2.1 Migración interna de menores de 5 años

Los saldos migratorios de los nacidos en dichos períodos de referencia, o sea, menores de 5 años, fueron calculados con métodos aproximados, en base a las razones niño-mujer por provincia, estas relaciones niño-mujer se obtienen de los mismos censos.

Las migraciones netas de los menores de 5 años fueron calculadas con la siguiente ecuación:

$$M_{0-4} = \frac{1}{4} * (CWR_0 * \text{Mujeres}_{\text{migrantes (15-44)}})$$

Donde

M_{0-4} : son los migrantes para las edades de 0 a 4 años.

⁶ Representa el número de migrantes netos por cada 100 migrantes brutos.

CWR_0 : son las razones de hijos en edades de 0 a 4 años, con las mujeres con edades de 15 a 44 años.

$$CWR_0 = \text{Población}_{(0-4)} / \text{Mujeres}_{(15-44)}$$

A estos saldos netos migratorios, basados en la información censal, se hicieron los ajustes por omisión, en los mismos niveles de sexo y edad que a la población total del país.

3. PROYECCIÓN DE LOS COMPONENTES DEMOGRÁFICOS

3.1 Mortalidad infantil

Se hicieron estimaciones de la mortalidad infantil por sexo, para el año 2010 y para cada una de las regiones demográficas que anteriormente se han definido. Este indicador, junto a la mortalidad general y la población censada, nos va a permitir derivar las tablas de vida iniciales para el período de la proyección.

Cuadro 4

REPÚBLICA DOMINICANA: Estimación de la mortalidad infantil por sexo, según región. 2010.

Región	Mortalidad Infantil	
	Hombres	Mujeres
Total país	31.60	23.70
Región 1	30.34	21.92
Región 2	30.63	23.78
Región 3	32.72	25.13
Región 4	33.23	25.05
Región 5	34.53	27.00

Para la proyección de la mortalidad infantil se ha utilizado una curva logística que tiene como pivotes: la mortalidad infantil para cada sexo y región en el año 2010, y una estimación de la mortalidad infantil para el año 2030. La curva logística utilizada en la proyección de la mortalidad infantil es:

$$q_0(t) = k_1 + \frac{k_2}{1 + e^{(a+bt)}}$$

En la que:

k_1 = límite inferior de la mortalidad infantil: 5 por cada mil nacidos vivos (para ambos sexos).

k_2 = límite superior de la mortalidad infantil: 160 por cada mil nacidos vivos (para ambos sexos).

a y b = son parámetros que dependen de los pivotes elegidos.

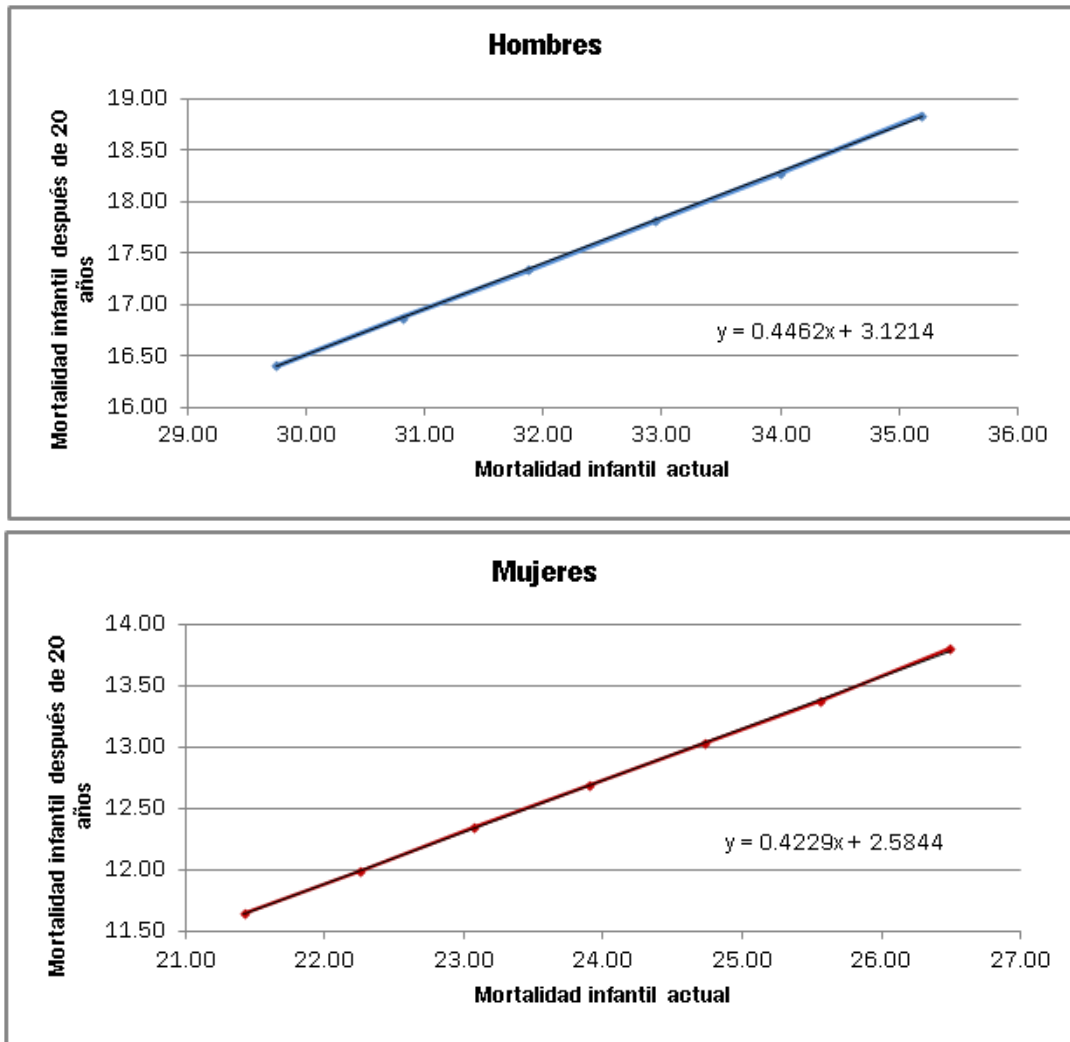

Pivote 1= nivel de la mortalidad infantil al inicio (2010).

Pivote 2= estimación de la mortalidad infantil dentro de veinte años (en el 2030).

La estimación de la mortalidad infantil para el año 2030 se determinó teniendo en cuenta el comportamiento que ha tenido este indicador en el país, y su perspectiva a futuro que fue estimada para la proyección nacional. El modelo de comportamiento de la mortalidad infantil en el país se ilustra en el gráfico siguiente:

Gráfico 6

REPÚBLICA DOMINICANA: Comportamiento de la mortalidad infantil entre un nivel actual y dentro de 20 años.

Con esta información se proyectó la mortalidad infantil de las regiones, y para cada sexo, en los diferentes periodos que abarca esta proyección a nivel sub-nacional. Se prevé que la mortalidad infantil seguirá su proceso de descenso, y que al final del periodo que abarca la proyección ésta ronde un promedio de dieciséis defunciones por cada mil nacidos vivos.

Cuadro 5

REPÚBLICA DOMINICANA: Mortalidad infantil proyectada por sexo, según región

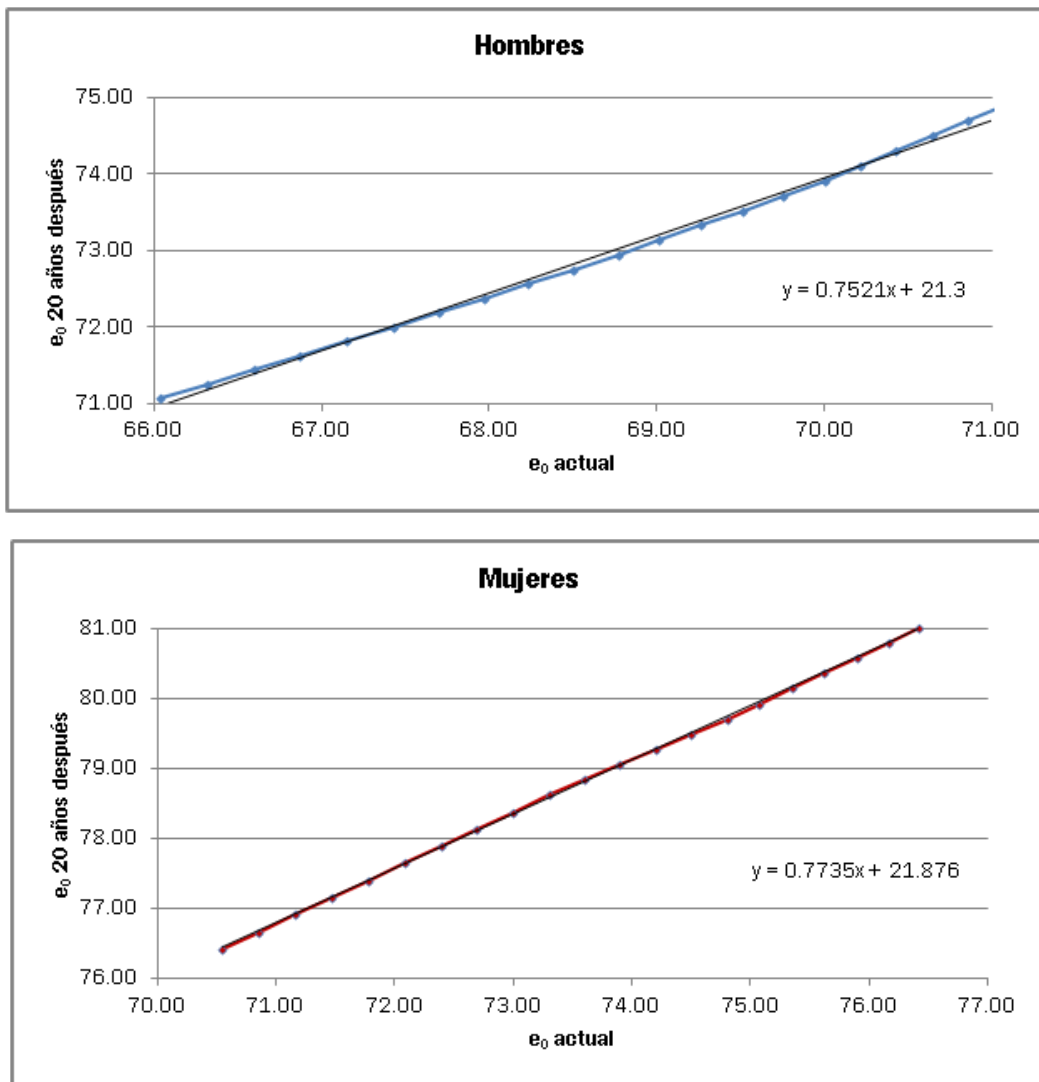

Región	2010-2015		2015-2020		2020-2025		2025-2030	
	Hombres	Mujeres	Hombres	Mujeres	Hombres	Mujeres	Hombres	Mujeres
Región 1	28.11	20.17	24.12	17.15	20.74	14.68	17.90	12.70
Región 2	28.37	21.85	24.33	18.52	20.91	15.79	18.04	13.58
Región 3	30.28	23.07	25.92	19.51	22.21	16.59	19.08	14.22
Región 4	30.75	23.00	26.30	19.45	22.52	16.54	19.34	14.18
Región 5	31.93	22.00	27.29	18.64	23.32	15.89	19.99	13.66

3.2 Esperanza de vida al nacer

Para la proyección de la esperanza de vida al nacer se procedió a determinar los pivotes a ser utilizados en la curva logística. Como pivote inicial se ha utilizado la determinada para cada región en las tablas de vida, construidas con la información del *Censo de población y vivienda del año 2010*. Y, como segundo pivote, la esperanza de vida que se espera tenga la población para cada región, dentro de veinte años (en el 2030), para determinar este segundo pivote se hizo una relación de las esperanzas de vida estimadas y proyectadas para el total del país en las proyecciones nacionales (1950 -2100), con la correspondiente esperanza de vida veinte años después; de esta relación, se obtuvo para cada sexo las curvas siguientes:

Gráfico 7

REPÚBLICA DOMINICANA: Comportamiento de la esperanza de vida al nacer entre un nivel actual y veinte años después.

La curva logística utilizada en la proyección de la esperanza de vida al nacer es:

$$e_0(t) = k_1 + \frac{k_2}{1 + e^{(a+bt)}}$$

k_1 = límite inferior de la esperanza de vida al nacer: 40 años (para ambos sexos).

k_2 = límite superior de la esperanza de vida al nacer: 94 años para las mujeres y 89 para los hombres.

Los resultados de la esperanza de vida al nacer, para cada uno de los periodos, y sexo de las diferentes regiones, fueron:

Cuadro 6

REPÚBLICA DOMINICANA: Esperanza de vida al nacer proyectada por sexo, según región.

Región	2010-2015		2015-2020		2020-2025		2025-2030	
	Hombres	Mujeres	Hombres	Mujeres	Hombres	Mujeres	Hombres	Mujeres
Región 1	68.16	72.83	69.32	74.26	70.46	75.65	71.57	76.99
Región 2	70.64	76.00	71.65	77.25	72.63	78.45	73.58	79.60
Región 3	70.37	75.58	71.40	76.85	72.39	78.08	73.36	79.25
Región 4	70.58	74.31	71.59	75.65	72.57	76.95	73.53	78.20
Región 5	71.35	74.50	72.31	75.89	73.24	77.22	74.15	78.50

Con el juego de tablas de vida, realizadas para cada región del país, para el año 2010, y conciliadas éstas con la tabla de vida nacional para ese mismo año, se procedió a la elaboración de las tablas de vida por sexo y período para cada región. Esta labor se hizo mediante la utilización de las planillas del paquete PAS, del Buró del Censo de los Estados Unidos, que es un sistema de hojas de cálculo para el análisis demográfico de población; con las planillas INTLTF se interpolan las tablas femeninas, y con la INTLTM las masculinas, entre una tabla inicial (que son las obtenidas para el 2010) y una tabla de vida límite, en este caso las usadas en las proyecciones nacionales con esperanzas de vida de 89 y 93 años, para hombres y mujeres respectivamente.

Con la interpolación de las tablas de vida se obtienen, para cada periodo y sexo, las tasas de mortalidad asociadas a las esperanzas de vida al nacer proyectadas.

3.3 Nivel y estructura de la fecundidad

Como se expuso anteriormente, la fecundidad fue medida, en su nivel, por la tasa global de fecundidad (TGF), y en su estructura, por las tasas específicas. Los valores iniciales corresponden al censo de 2010.

La proyección de la TGF se hizo mediante una curva logística, de manera similar a como se hizo en el caso de la esperanza de vida al nacer y la mortalidad infantil (ya explicadas anteriormente).

Con la fecundidad, los datos permitieron una proyección por provincia, sin necesidad de agruparlas en las cinco regiones demográficas, como en el caso de la mortalidad.

La TGF fue proyectada usando una curva logística de la siguiente forma:

$$TGF(t) = k_1 + \frac{k_2}{1 + e^{(a+bt)}}$$

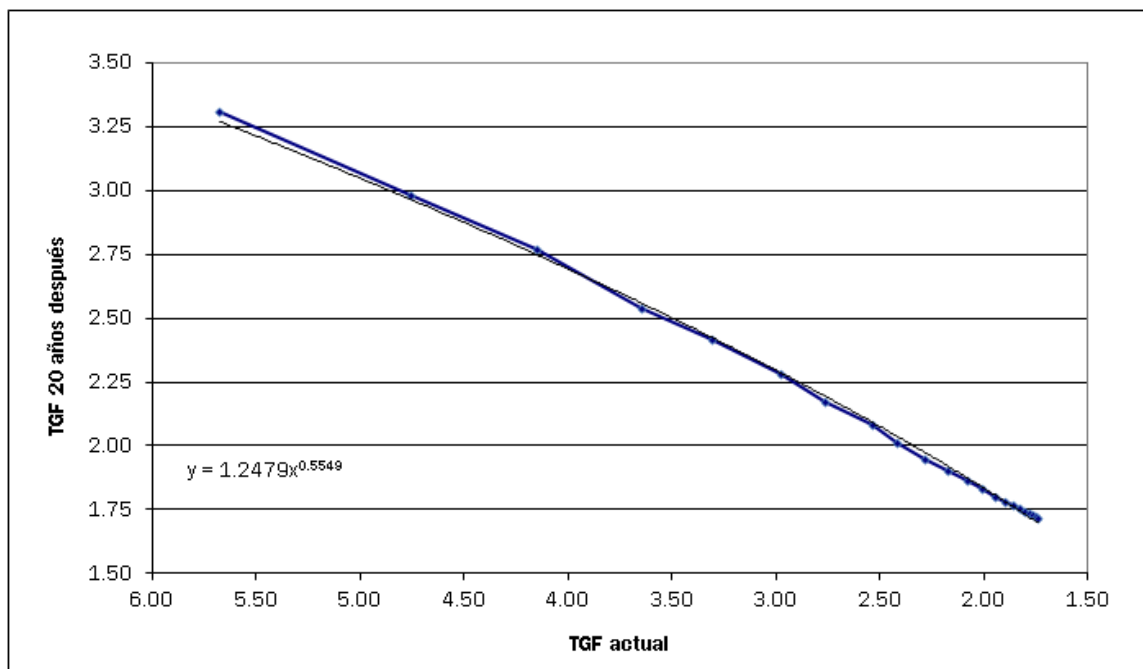

k_1 = límite inferior de la TGF: ocho hijos por mujer.

K_2 = límite superior de la TGF: 1.8 hijos por mujer.

Para la fijación de un valor de la tasa global de fecundidad en una fecha futura, dentro de veinte años, se usó la relación de los niveles de la TGF (de la proyección para el total país) con su homólogo veinte años después, donde se obtiene una curva presentada en el gráfico a continuación.

Gráfico 8

REPÚBLICA DOMINICANA: Comportamiento de la TGF, entre un nivel actual y 20 años después.

San José de Ocoa	2.53	2.38	2.26	2.16
Santo Domingo	2.42	2.27	2.16	2.07

Las tasas de la fecundidad por edad ($f(x,n)$), proyectadas, se determinaron a partir del modelo relacional de Gompertz, tomando como estructura base la estimada para cada provincia, por el Método P/F5 del censo de 2010, y como estándar el Modelo 10 de la Organización de las Naciones Unidas, con un nivel de fecundidad (TGF de 1.60). De esta manera se logra una mejor coherencia entre la evolución de la estructura observada en el período histórico, y la del período de proyección.

Modelo límite de Fecundidad. Modelo M10 de la Organización de las Naciones Unidas

⁷ Manual X de la Organización de las Naciones Unidas (1983).

El modelo relacional de Gompertz tiene la particularidad de que permite describir el comportamiento de la fecundidad acumulada de las mujeres en edad fértil, según su edad, mediante una función que utiliza solo dos parámetros: uno se vincula con la edad media de las mujeres al momento de ocurrir los nacimientos; el otro se asocia al grado de concentración con que ocurre el proceso de reproducción de la población.

3.4 Migración

3.4.1 Migración internacional por provincia

Como se explicó anteriormente (punto 2.4.1), los saldos internacionales se obtuvieron con la distribución por sexo y edad del saldo migratorio internacional total de las proyecciones nacionales y proporcionalmente a la población por sexo y edad de cada provincia.

Los saldos migratorios internacionales del total del país se fueron distribuyendo proporcionalmente a la población provincial resultante de la proyección de cada periodo.

3.4.2 Migración interna por provincia

El cálculo de los saldos migratorios internos por provincia, de los periodos 1997-2002 y 2005-2010 está explicado en el punto 2.4.2. A partir del año 2010, en la proyección, se mantuvo la misma estructura de los saldos migratorios por sexo y edad de ese período para las provincias.

Se hizo la hipótesis de una disminución paulatina de los saldos migratorios, de tal manera que en cada periodo sucesivo se redujeron los saldos migratorios de las provincias en un 5% con respecto al período anterior.

4. PROYECCIÓN

4.1 Proyección de las poblaciones de las provincias

Organizada toda la información necesaria se procedió a la realización de las proyecciones provinciales, y fue aplicado a cada una de ellas el *Método de los Componentes*, o sea, fue hecha una proyección específica para cada provincia a partir de 2010.

El *Método de los Componentes* consiste según el principio básico de la ecuación compensadora, en aplicar fórmulas matemáticas y técnicas estadísticas que relacionan una población base por sexo y edad, que es el punto de partida, con las hipótesis elaboradas de mortalidad, fecundidad y una hipótesis de migración.

$$N_{t+a} = N_t + B_{t,t+a} - D_{t,t+a} + M_{t,t+a}$$

N_{t+a} es la población al final del período.

N_t es la población en el instante o población de partida.

$B_{t,t+a}$ son los nacimientos ocurridos durante el período de evaluación.

$D_{t,t+a}$ son las defunciones ocurridas durante el período de evaluación.

$M_{t,t+a}$ son los migrantes netos (inmigrantes menos emigrantes) del período de evaluación.

La mortalidad de las provincias fue obtenida a partir de las tablas de mortalidad elaboradas para cada una de las regiones demográficas, aplicándole a cada provincia la mortalidad de la región dentro de la cual estaba incluida. Las otras variables demográficas fueron las estimadas específicamente para cada provincia.

Para la determinación de la población por sexo y edad del período comprendido entre el año 2000 y 2010 se hizo una conciliación entre las poblaciones de las provincias que resultaron de los censos de 2002 y 2010, estas poblaciones fueron trasladadas a mitad de año del 2000 y del 2010 y ajustadas con la población resultante para esos años de la proyección nacional para esos años.

4.2 Conciliación entre la proyección de las provincias y la nacional

Hecha la proyección de la población de cada provincia por separado y mediante la utilización del *Método de los Componentes* y siempre teniendo en cuenta tomar las previsiones de lugar para que haya coherencia entre las variables provinciales y las nacionales, la suma de todas las poblaciones provinciales regularmente arroja pequeñas diferencias con respecto a la población de la proyección nacional, puesto que éstas son calculadas de forma independiente.

Por este motivo, la proyección fue hecha en etapas, correspondientes a los cuatro quinquenios de la proyección (2010-2015, 2015-2020, 2020-2025 y 2025-2030), y al final de cada una de estas etapas fueron hechos pequeños ajustes de conciliación con el total nacional.

4.3 Población por grupos de edad y año calendario

Luego de obtenidas todas las poblaciones que cubren el periodo de la proyección (2000-2030), se calcularon las poblaciones por años calendario y por grupo de edad y sexo, mediante la interpolación de las poblaciones por edad y sexo obtenidas para los años terminados en 0 y 5.

Estas primeras poblaciones por año calendario, edad y sexo de cada provincia, fueron conciliadas con las calculadas para cada año a nivel nacional, mediante prorrato con la utilización el método de la tabla cuadrada. El método de la tabla cuadrada permite desglosar una población global en grupos de edades, a partir de prorratos horizontales y verticales sucesivos.

5. RESULTADOS

RESULTADOS DE LAS ESTIMACIONES Y PROYECCIONES PROVINCIALES DE POBLACIÓN 2000-2030
